---

# Overview

---

Precurio is built on the Zend Framework (version 1.11), and therefore an understanding of Zend Framework is required to make sense of how Precurio works.

Precurio Workflow is a simplified business process management system (BPM) and contains components such as system schemas, form template and the process manager.

The Process Manager controls the flow of the forms from one user to the other. I.e. it contains the algorithm that determines which user gets to approve a particular step of the workflow, based on configuration.

The Schemas component contains XML schema files and a processor. This component controls how the form inputs behave and their positions.

Form Templates is a simple structure component that defines a complete form as containing a Header, the actual Form and Footer.

The Tasks component works hand in hand with the Process Manager. Each step of the process is essentially a task that needs to be completed (approved or declined).
